DNA/protein labeling can occur using a variety of tags, including Chd/sd-Cas9, Cas9[m3i\] and Fok1 nuclease. This approach has been used to detect cell-cell contacts by the random ligation of barcoded RNAs to ssDNA isotherms, \*i.e.\* a method called barcoded RNA-seq.^[@cit1]^ The advantage of barcoded RNA-seq is that it is not affected by RNAi. It has also been used to examine the distribution of cell-cell junctions, such as desmosomes and hemidesmosomes, in reconstituted tissue-based models.^[@cit2]^ However, this technique is limited in its ability to study, \*e.g.\*, how an individual cell is affected by signals transmitted to it from neighboring cells, how cells divide or migrate into tissues, or how a cell adapts to its environment. A potential alternative to barcoded RNA-seq is the use of a molecular barcoding system which relies on the use of a DNA-binding fluorophore, such as G
